

Introduction to solaR

Oscar Perpiñán Lamigueiro

5 December 2010

1 Introduction

The solaR package includes a set of functions which calculate the solar radiation incident on a photovoltaic generator and simulate the performance of several applications of the photovoltaic energy. The current version of this package allows the whole calculation from both *daily* and *intra-daily* global horizontal irradiation to the final productivity of grid connected PV systems and water pumping PV systems. Besides, the package includes a tool for the statistical analysis of the performance of a large PV plant composed of several systems.

The package is constructed with S4 classes and methods. The time series are constructed with the zoo package [7].

2 Solar Geometry

The apparent movement of the Sun is defined with some equations included in the functions fSolD and fSolI. fSolD computes the daily apparent movement of the Sun from the Earth. This movement is mainly described (for the simulation of photovoltaic systems) by the declination angle, the sunset angle and the daily extra-atmospheric irradiation. On the other hand, fSolI computes the angles which describe the intra-daily apparent movement of the Sun from the Earth.

The next example shows these calculations for a certain day:

```
> BTd = fBTd(mode = "serie")
> lat = 37.2
> SolD <- fSolD(lat, BTd[100])
> SolI <- fSolI(SolD, sample = "hour", keep.night = FALSE)
> head(SolI)

```

and for a set of days:

```
> SolD <- fSolD(lat, BTd[c(10, 50, 100)])
> print(SolD)

   decl    eo      ws Bo0d      EoT
2010-01-10 -0.3847 1.033 -1.258 4497 -0.035464
2010-02-19 -0.2082 1.022 -1.410 6327 -0.059933
2010-04-10  0.1315 0.995 -1.671 9541 -0.004637
attr("lat")
[1] 37.2
```

With the function fBTd it is possible to get time bases with different structures. Thus, the calculations for the so called “average days” need the next piece of code, with the result displayed in the figure 1.

```
> lat = 37.2
> SolD <- fSolD(lat, BTd = fBTd(mode = "prom"))
> SolI <- fSolI(SolD, sample = "10 min", keep.night = FALSE)
```

These calculations can also be carried out for the whole year (figure 2).

```

> mon = month.abb
> p <- xyplot(AIS * 180/pi ~ AzS * 180/pi, groups = month, data = SolI,
+   type = "l", col = "black", xlab = expression(psi[s]), ylab = expression(gamma[s]))
> plab = p + glayer(panel.text(0, y[x == 0], mon[group.value],
+   pos = 4, cex = 0.8))
> print(plab)

```

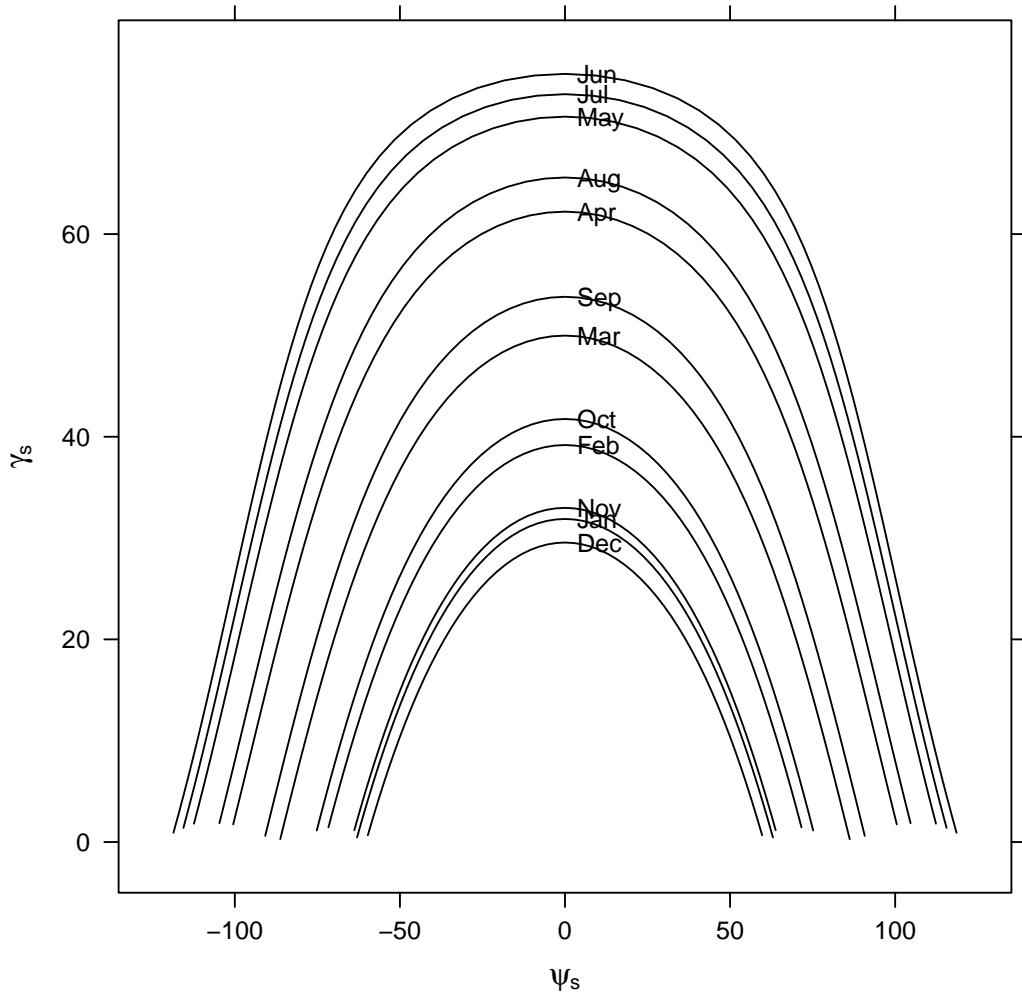

Figure 1: Azimuth and height solar angles during the “average days”.

```

> BTd = fBTd(mode = "serie")
> sold <- fSolD(lat, BTd)
> summary(sold)

```

These two functions have been included in a new function, `calcSol`. This function constructs an object of class `Sol` containing in its slots the `zoo` objects created by `fSolD` and `fSolI`. This class owns methods for getting and displaying information (for example, `as.zooD`, `as.zooI`, `xyplot`).

3 Solar Radiation

Values of global horizontal irradiation are commonly available, either as monthly averages of daily values or as a time series of daily during one or several years. The analysis of the performance of a PV system starts from the transformation of the global horizontal irradiation to global, diffuse and direct horizontal irradiance and irradiation, and then irradiance and irradiation on the generator surface.

3.1 Irradiation and irradiance on the horizontal plane

The function `fCompD` extracts the diffuse and direct components from the daily global irradiation on a horizontal surface by means of regressions between the clearness index and the diffuse fraction parameters. This function need the results from `fSolD`, a set of values of global horizontal irradiation (Wh/m^2), and the correlation between the clearness index and the diffuse fraction. The current version of `solarR` includes several correlations (type `help(corrFdKt)` for details). Besides, the user may define a particular correlation through the argument `f`. Once again for a certain day:

```

> BTd = fBTd(mode = "serie")
> Sold <- fSolD(lat, BTd[100])
> SolI <- fSolI(Sold, sample = "hour")
> G0d = zoo(5000, index(Sold))
> fCompD(Sold, G0d, corr = "Page")

      Fd      Ktd     G0d     D0d     B0d
2010-04-10 0.4078 0.5241 5000 2039 2961

> fCompD(Sold, G0d, corr = "CPR")

2010-04-10 0.5582 0.5241 5000 2791 2209

```

and for the “average days”:

```

> lat = 37.2
> G0dm = c(2.766, 3.491, 4.494, 5.912, 6.989, 7.742, 7.919, 7.027,
+       5.369, 3.562, 2.814, 2.179) * 1000
> Rad = readG0dm(G0dm, lat)
> sold <- fSolD(lat, fBTd(mode = "prom"))
> fCompD(sold, Rad, corr = "Page")

      Fd      Ktd     G0d     D0d     B0d
2010-01-17 0.3354 0.5882 2766 927.6 1838

2010-12-13 0.4233 0.5104 2179 922.3 1257

```

Let's use `corr='user'` to define a function with the correlation of Page. Obviously, we shall obtain the same result as with `corr='Page'`.

```
> p <- xyplot(solD$decl)
> print(p)
```

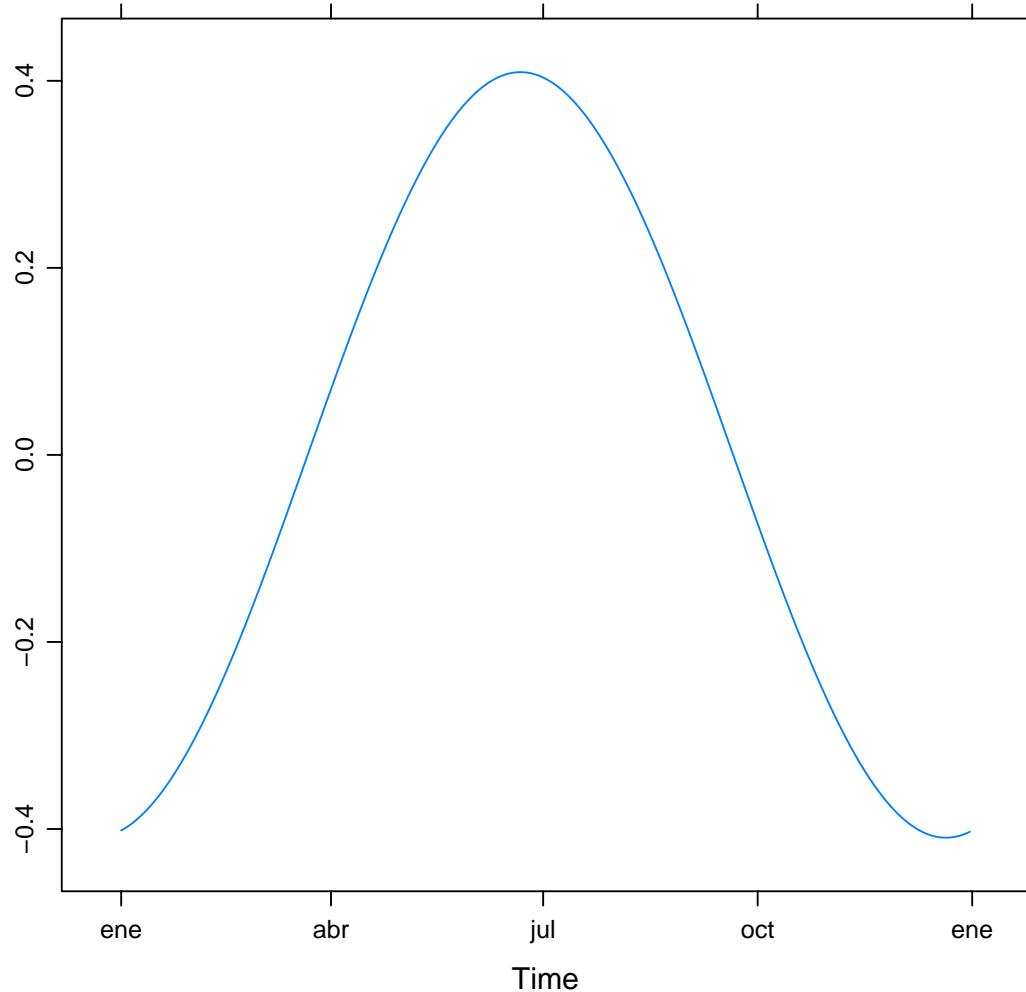

Figure 2: Declination throughout the year

```

> fKTd = function(x) {
+   (0.99 * (x <= 0.17)) + (x > 0.17) * (1.188 - 2.272 * x +
+     9.473 * x^2 - 21.856 * x^3 + 14.648 * x^4)
+ }
> fCompD(SolD, G0d, corr = "user", f = fKTd)

      Fd      Ktd    G0d    D0d    B0d
2010-04-10 0.5582 0.5241 5000 2791 2209

```

The daily profile of irradiance is obtained with the function `fCompI`. This function needs the information provided by `fCompD` and `fSolI` or `calcSol`. For example, the profiles for the “average days” are obtained with the next code (fig. 3).

```

> lat = 37.2
> sol <- calcSol(lat, fBTd(mode = "prom"), sample = "hour", keep.night = FALSE)
> G0dm = c(2.766, 3.491, 4.494, 5.912, 6.989, 7.742, 7.919, 7.027,
+         5.369, 3.562, 2.814, 2.179) * 1000
> Ta = c(10, 14.1, 15.6, 17.2, 19.3, 21.2, 28.4, 29.9, 24.3, 18.2,
+       17.2, 15.2)
> BD <- readG0dm(G0dm = G0dm, Ta = Ta, lat = 37.2)
> compD <- fCompD(sol, BD, corr = "Page")
> compI <- fCompI(sol, compD)
> summary(compI)

3.1.1 Meteorological data

There are several functions to construct a `Meteo` object with radiation and temperature data. For daily data, if it is stored in a local file or a `data.frame`, the functions `readBD` and `df2Meteo` are recommended, while `readG0dm` is indicated when only 12 monthly means are available. For intradaily data the correspondent functions are `readBDi` and `dfI2Meteo`. Besides, `zoo2Meteo` can construct a `Meteo` object from a `zoo` object both for daily and intradaily data.

For example, the `helios` dataset included in the package, obtained from <http://helios.ies-def.upm.es>, can be converted to a `Meteo` object with the next code:

```

> data(helios)
> names(helios) = c("date", "G0", "TempMax", "TempMin")
> bd = df2Meteo(helios, dates.col = "date", lat = 41, source = "helios-IES",
+   format = "%Y/%m/%d")
> summary(getData(bd))

Index          G0          TempMax        TempMin

3rd Qu.:2009-10-03 12:00:00 3rd Qu.: 7140 3rd Qu.:31.06 3rd Qu.: 15.11
Max.   :2009-12-31 00:00:00 Max.   :11254 Max.   :38.04 Max.   : 24.80

```

On the other hand, the function `readMAPA` is able to download the meteorological data available at www.mapa.es/siar. This webpage provides daily measurements from a set of agroclimatic stations located in Spain. This function needs the code of the station and its province, and the start and end date. The codes of stations and provinces are stored at the dataset `RedEstaciones`. For example, there are several stations in Madrid:

```

> data(RedEstaciones)
> Madrid <- subset(RedEstaciones, NomProv == "Madrid")
> print(Madrid)

  Provincia Estacion NomProv           NomEst
P209      28        1 Madrid Center:_Finca_experimental
P210      28        2 Madrid                  Arganda
P211      28        3 Madrid                 Aranjuez
P212      28        4 Madrid  Fuentidueña_de_Tajo
P213      28        5 Madrid San_Martin_de_la_Vega
P214      28        6 Madrid                  Chinchon
P215      28       102 Madrid Villa_del_Prado

```

```

> p <- xyplot(G0 + B0 + D0 ~ w | month, data = compI, type = "l",
+               auto.key = list(space = "right"))
> print(p)

```

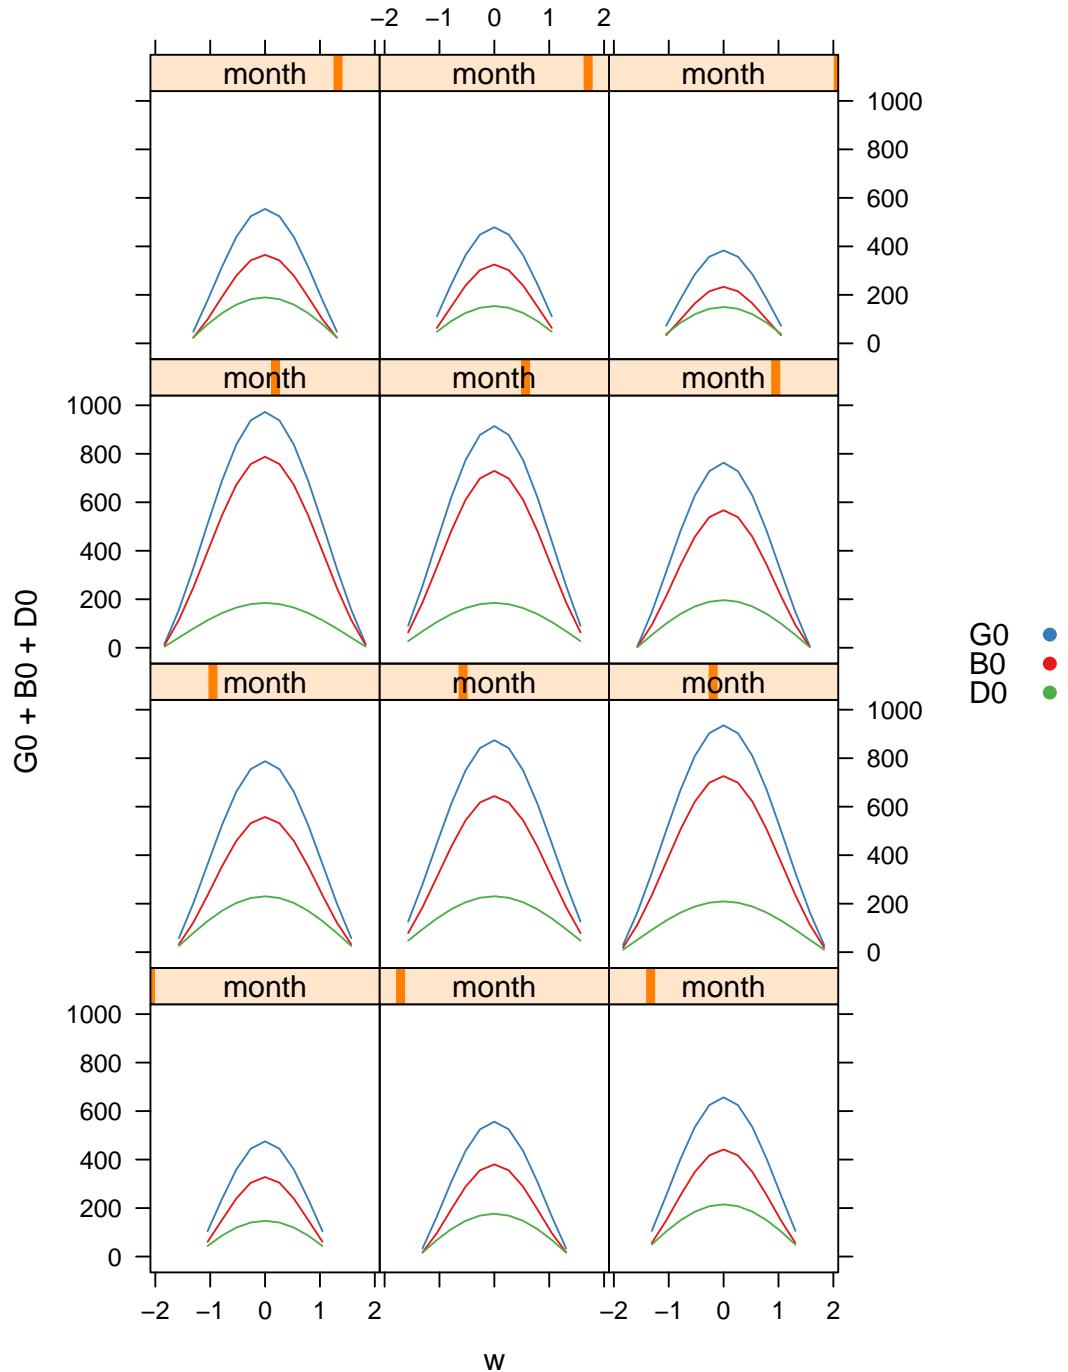

Figure 3: Global, diffuse, and direct irradiance during the “average days”.

`readMAPA` constructs an object of class `Meteo`. The data is obtained with the method `getData`. If only the irradiation series is needed, the method `getG0` is recommended.

For example, let's obtain the 2009 data from the station at Aranjuez (fig. 4). It is important to note that the radiation measurements available at the webpage are in MJ/m^2 , but `readMAPA` converts the values to Wh/m^2 :

```
> Aranjuez <- readMAPA(28, 3, "01/01/2009", "31/12/2009")

Downloading data from www.mapa.es/siar...

> print(Aranjuez)

This database includes information of maximum and minimum values of temperature. The function `fTemp` calculates a profile of the ambient temperature with this information following the method proposed in [2]. The evolution of this synthetic temperature during March is displayed in the figure 5.

```
> lat = 41
> sol = calcSol(lat, BTd = indexD(Aranjuez), sample = "hour")
> Temp <- fTemp(sol, Aranjuez)
```

3.1.2 The function `calcG0`

The previous steps are included in the function `calcG0`. For example, with the next code, the components of horizontal irradiation and irradiance are obtained from the measurements of the meteorological station of Aranjuez (figure 6).

```

> p = xyplot(G0 ~ TempMedia | month, data = Aranjuez, type = c("p",
+ "r"))
> print(p)

```

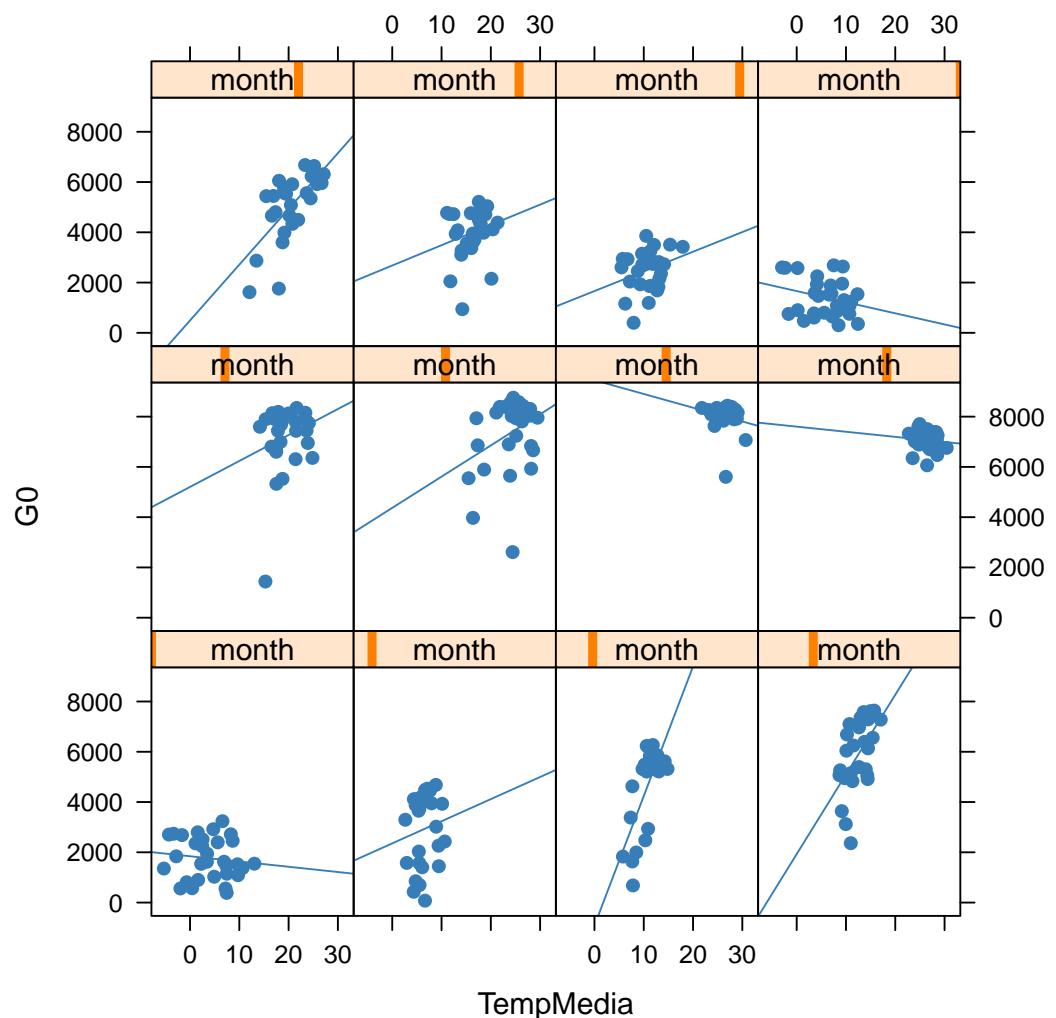

Figure 4: Daily irradiation and mean temperature in the station of Aranjuez.

```

> wTemp = window(Temp, start = as.POSIXct("2009-03-01"), end = as.POSIXct("2009-03-31"))
> p = xyplot(wTemp, col = "black", ylab = "T") + layer_(panel.xblocks(x,
+   DoY, col = c("lightgray", "white")))
> print(p)

```

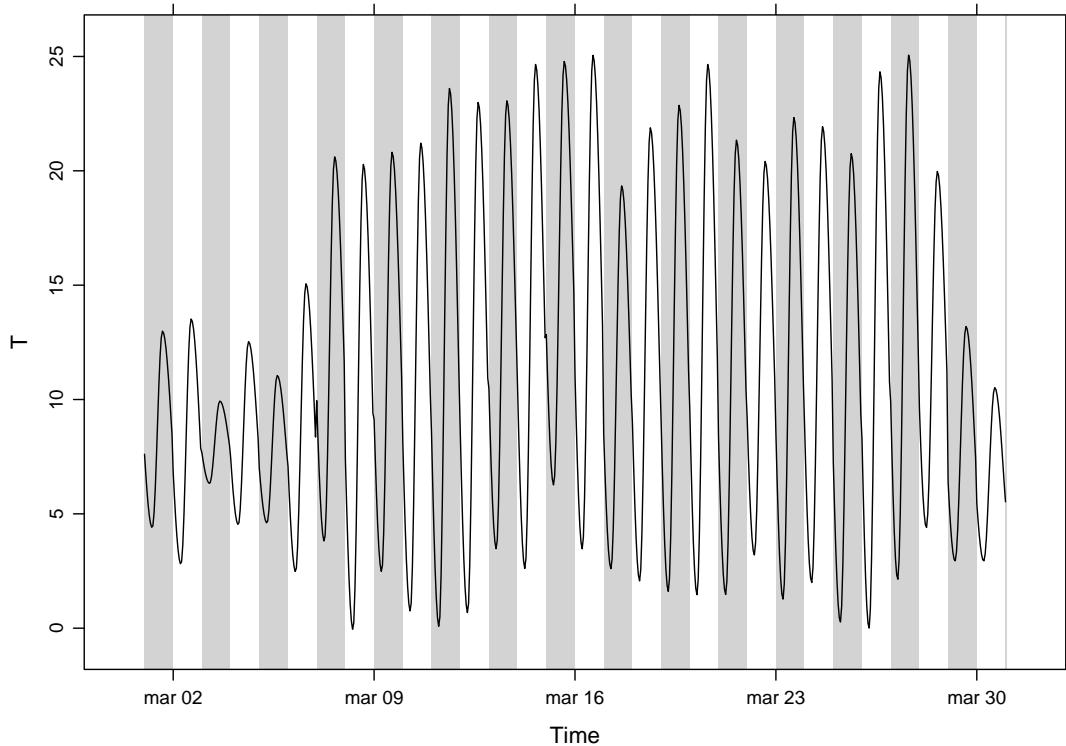

Figure 5: Evolution of the ambiente temperature during March 2009 in Aranjuez.

```

> g0 <- calcG0(lat = 37.2, modeRad = "mapa", mapa = list(prov = 28,
+   est = 3, start = "01/01/2009", end = "31/12/2009"))

Downloading data from www.mapa.es/siar...

> print(g0)

```

With this version, solaR accepts intradaily irradiation data sources.

For example, the Measurement and Instrumentation Data Center of the NREL (NREL-MIDC) provides meteorological data from a variety of stations. We will try the *La Ola - Lanai* station at Hawaii (http://www.nrel.gov/midc/la_ola_lanai/).

```

> file = "http://www.nrel.gov/midc/apps/plot.pl?site=LANAI&start=20090722&edy=19&emo=11&eyr=2010&zenloc=19&year=2010&month=11&day=1&endyear=2010&em
> dat <- read.table(file, header = TRUE, sep = ",")
> lat = 20.77
> lon = -156.9339

```

First, we have to change the names of the columns and calculate the horizontal direct irradiation, since only the normal direct irradiation is included in the file.

```

> names(dat) <- c("date", "hour", "G0", "B", "D0", "Ta")
> dat$B0 <- dat$G0 - dat$D0

```

The datalogger program runs using Greenwich Mean Time (GMT), and data is converted to Hawaiian Standard Time (HST) after data collection. With local2Solar we can calculate the Mean Solar Time of the index.

```

> idxLocal <- with(dat, as.POSIXct(paste(date, hour), format = "%m/%d/%Y %H:%M",
+   tz = "HST"))
> idx <- local2Solar(idxLocal, lon = lon)

```

Therefore, the object Meteo is obtained with (figure 7):

```

> z <- zoo(dat[, c("G0", "D0", "B0", "Ta")], idx)
> NRELMeteo <- zoo2Meteo(z, lat = lat)

```

With this data, a G0 object can be calculated. First, the direct and diffuse components of the data are used (corr='none'):

```

> gONREL <- calcG0(lat = lat, modeRad = "bdI", bdI = NRELMeteo,
+   corr = "none")

```

If these components were not available, a fd-kt hourly correlation is needed (figure 8). For example:

```

> gOBRL <- calcG0(lat = lat, modeRad = "bdI", bdI = NRELMeteo,
+   corr = "BRL")

```

```
> p = xyplot(g0)
> print(p)
```

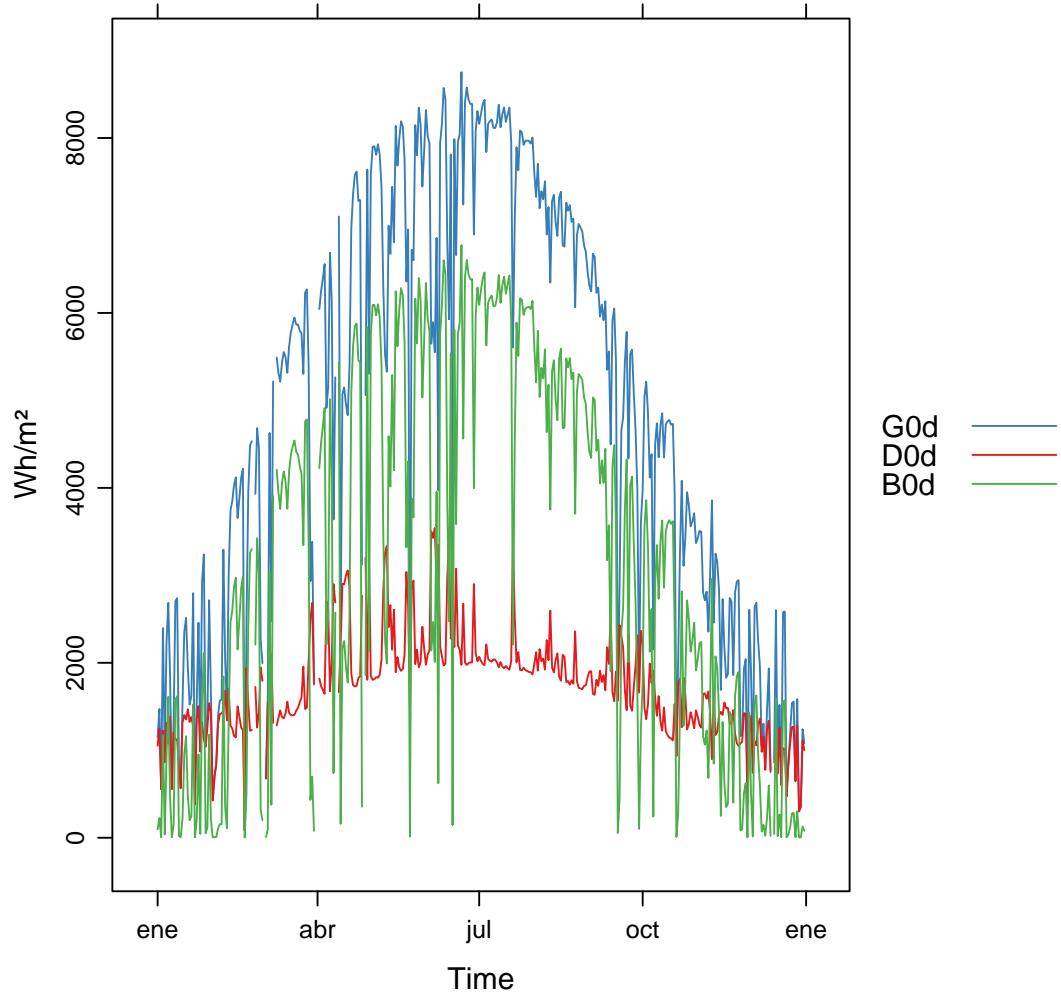

Figure 6: Components of horizontal irradiation calculated with calcG0.

```
> p <- xyplot(NRELMeteo)
> print(p)
```

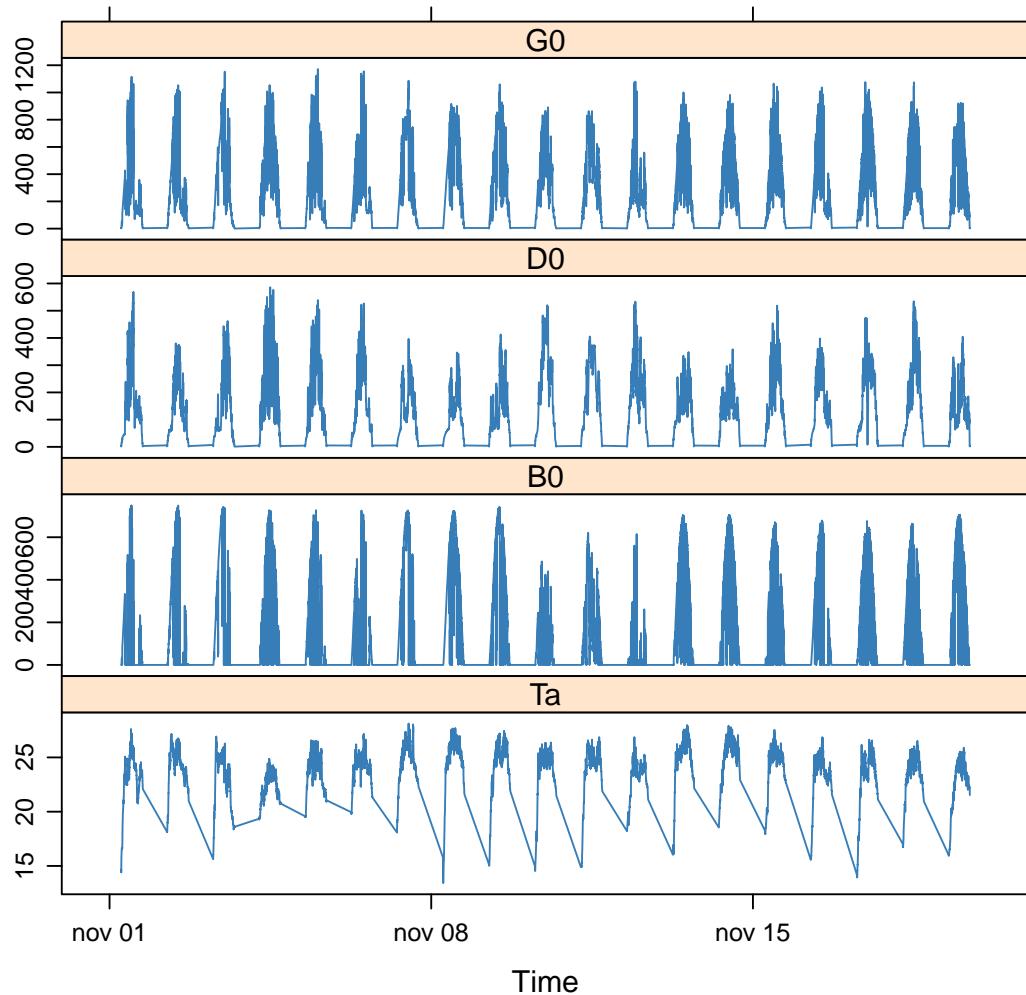

Figure 7: 1-min irradiation data from NREL-MIDC

```
> p <- xyplot(fd ~ kt, data = g0BRL, pch = 19, alpha = 0.3, cex = 0.5)
> print(p)
```

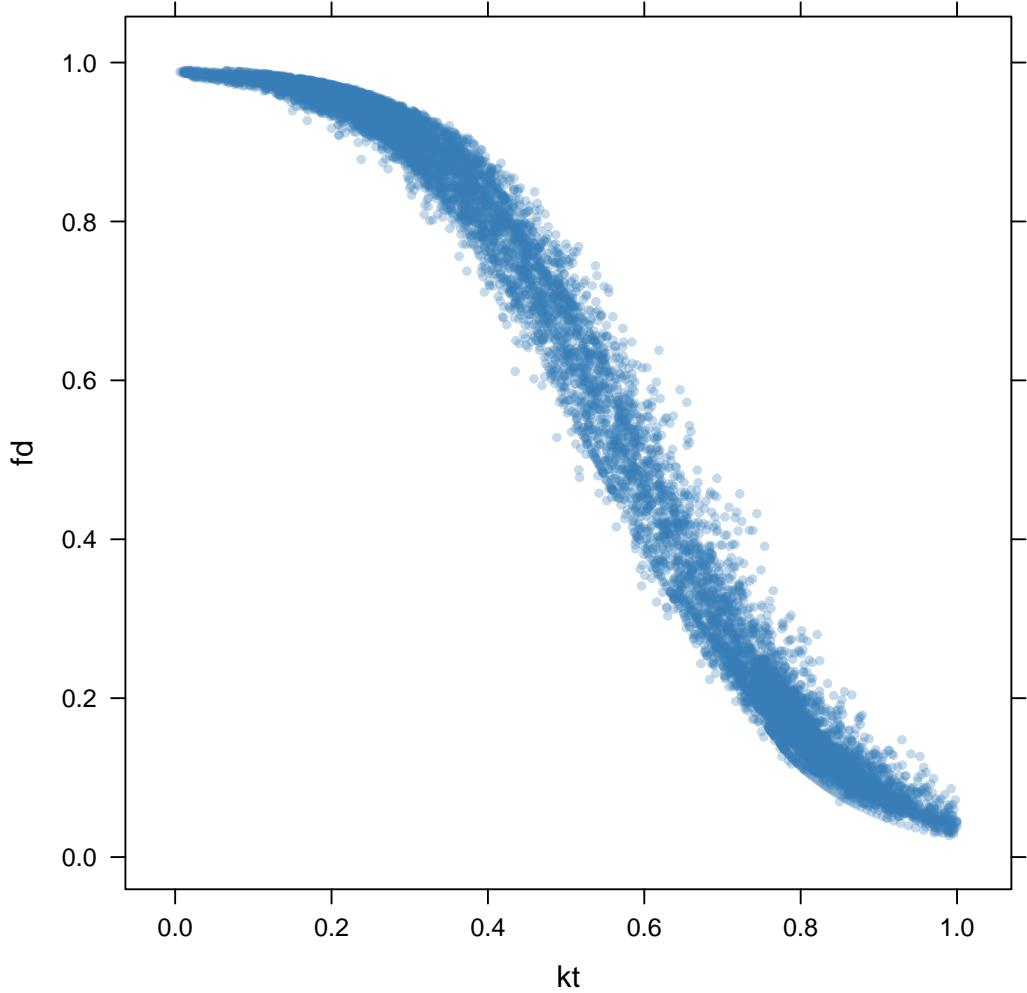

Figure 8: Diffuse fraction and clearness index correlation following the BRL model, with data from NREL-MIDC

3.2 Irradiation and irradiance on the generator plane

The solar irradiance incident on an inclined surface can be calculated from the direct and diffuse irradiance on a horizontal surface, and from the evolution of the angles of the Sun and the surface. The transformation of the direct radiation is straightforward since only geometric considerations are needed. However, the treatment of the diffuse irradiance is more complex since it involves the modelling of the atmosphere. There are several models for the estimation of diffuse irradiance on an inclined surface. The one which combines simplicity and acceptable results is the proposal of Hay and McKay. This model divides the diffuse component in isotropic and anisotropic whose values depends on a anisotropy index. On the other hand, the effective irradiance, the fraction of the incident irradiance that reaches the cells inside a PV module, is calculated with the losses due to the angle of incidence and dirtiness. This behaviour can be simulated with a model proposed by Martin and Ruiz requiring information about the angles of the surface and the level of dirtiness [3].

The orientation, azimuth and incidence angle are calculated from the results of fSolI or calcSol with the functions fTheta fInclin. These functions can calculate the movement and irradiance for fixed systems, and two-axis and horizontal N-S trackers. Besides, the the movement of a horizontal NS tracker due to the backtracking strategy [4] can be calculated with information about the tracker and the distance between the trackers included in the system.

Both functions are integrated in calcGef, which construct an object of class Gef. Once again, this class owns methods for obtaining and displaying information.

For example, with the previous results, we can calculate the irradiance and irradiation on a fixed surface. The figure 9 shows the relation between the effective and incident irradiance versus the cosine of the angle of incidence for this system.

```
> gef <- calcGef(lat = 37.2, modeRad = "prev", prev = g0, beta = 30)
> print(gef)

+      modeShd = "bt", betaLim = 60, distances = distHoriz, struct = structHoriz)
```

4 Productivity of a Grid Connected PV System

From the previous irradiance calculations, the function fProd simulates the performance of a Grid Connected PV (GCPV) system paying attention to some parameters of the system (characteristics of the PV module and the inverter, the electrical arrangement of the PV generator, and the losses of the system).

For example, the electrical power, voltage and current of a certain PV system is calculated below.

```

> p <- xyplot(Gef/G ~ cosTheta | month, data = gef, type = c("p",
+   "smooth"), par.settings = custom.theme(pch = 19, alpha = 0.5,
+   cex = 0.4))
> print(p)

```

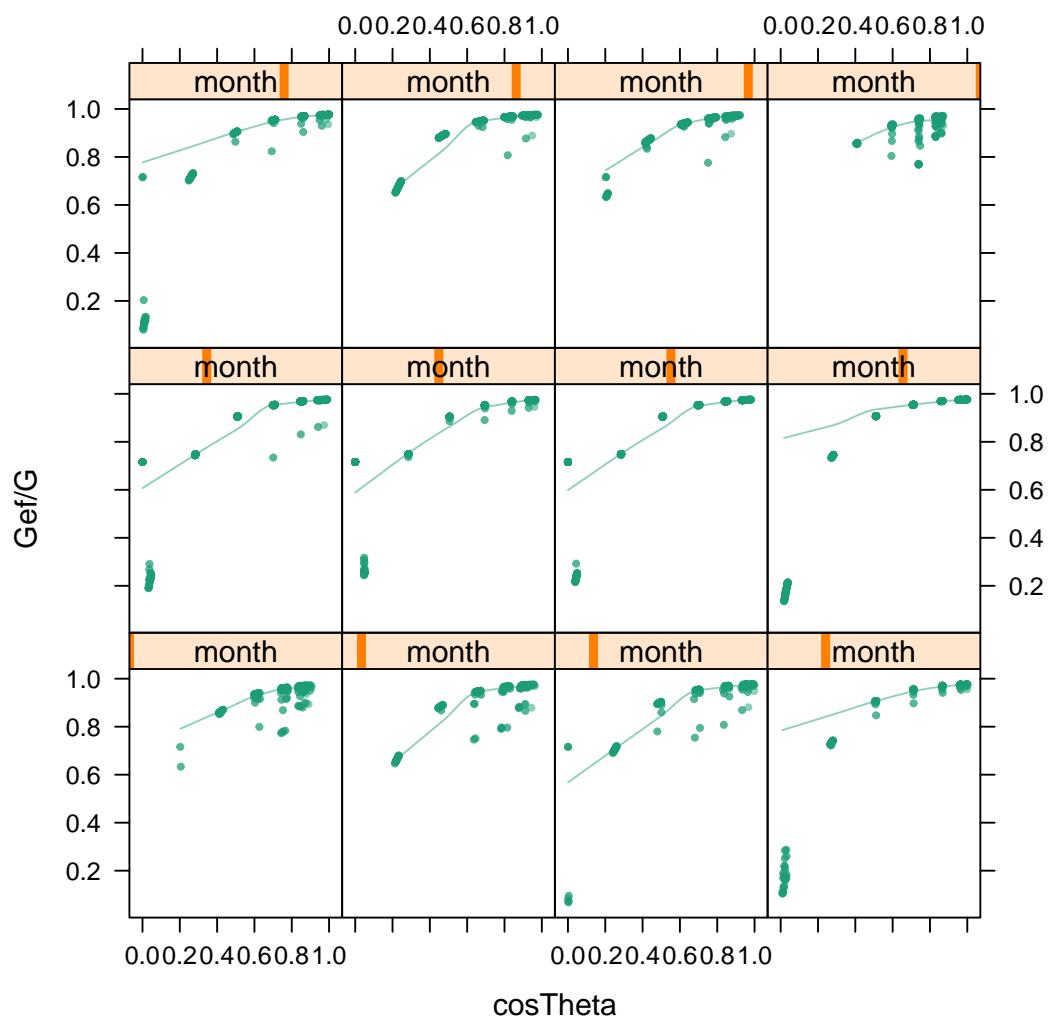

Figure 9: relation between the effective and incident irradiance versus the cosine of the angle of incidence for a fixed system.

```

> p <- xyplot(r2d(Beta) ~ r2d(w), data = gefBT, type = "l", xlab = expression(omega(degrees)),
+               ylab = expression(beta(degrees)))
> print(p)

```

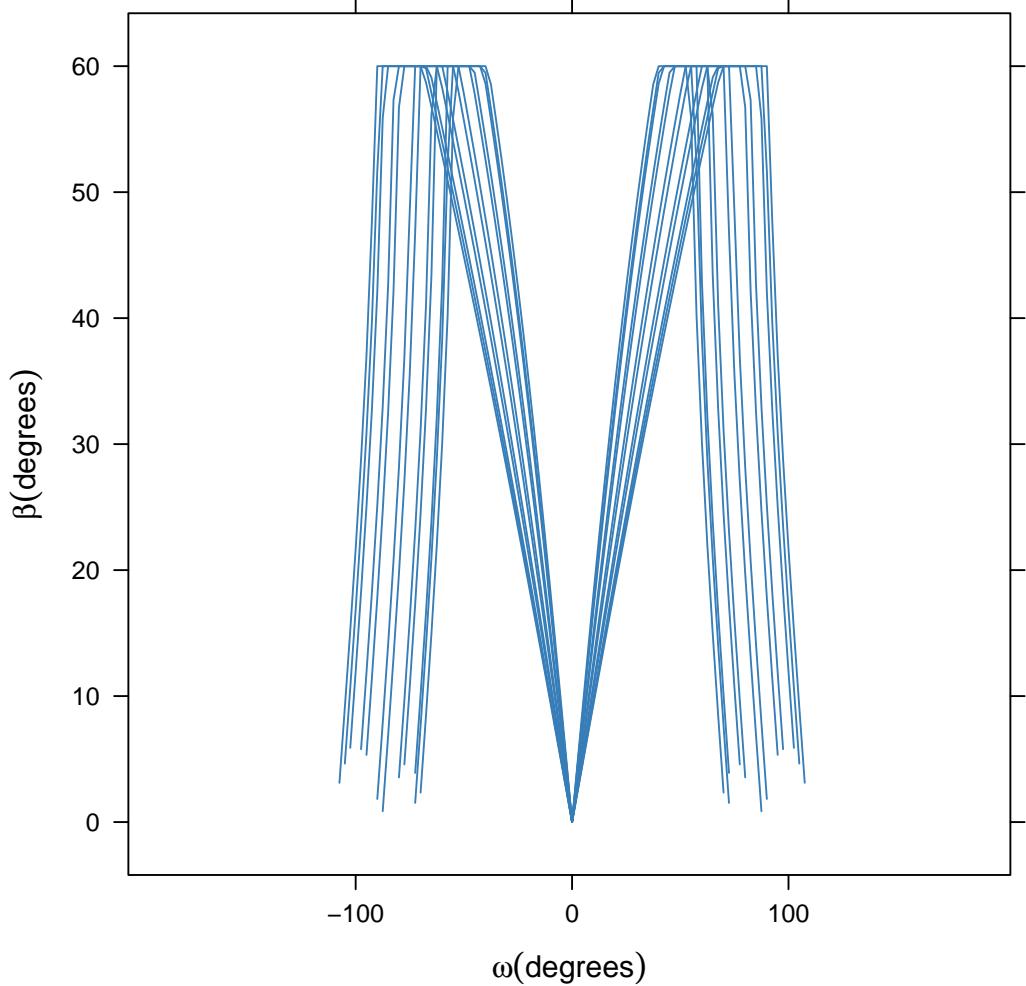

Figure 10: Evolution of the angle of inclination of a NS horizontal axis tracker with *backtracking* and limitation of angle.

```

> inclin = data.frame(Gef = c(200, 400, 600, 800, 1000), Ta = 25)
> fProd(inclin)

  Gef Ta   Tc   Voc   Isc   Vmpp   Impp   Vdc   Idc   Pac   Pdc   EffI

4 800 25 52.00 619.7 41.36 483.0 37.824 483.0 37.824 15323 16936 0.9325
5 1000 25 58.75 601.8 51.70 466.5 47.037 466.5 47.037 18342 20342 0.9293

```

First, `fProd` computes the Maximum Power Point (MPP) of the generator (`Vmpp` and `Impp`) at the irradiance and ambient temperature conditions contained in `Inclin`. Next, it checks that this points is inside the MPP window of the inverter, as defined by `inverter$Vmin` and `inverter$Vmax`). If the MPP value is outside this range, the function asigns the limit value to the voltage, and calculates the correspondent current value with a warning. Anyway, the inverter input voltage and current are `Vdc` e `Idc`:

```

> inclin = data.frame(Gef = 800, Ta = 30)
> gen1 = list(Nms = 10, Nmp = 11)
> prod = fProd(inclin, generator = gen1)
> print(prod)

  Gef Ta   Tc   Voc   Isc   Vmpp   Impp   Vdc   Idc   Pac   Pdc   EffI
1 800 30 57 505.3 41.36 392.3 37.68 420 33.83 11943 13169 0.9346

```

For this configuration, the losses due to the voltage limitation are:

```

> with(prod, Vdc * Idc/(Vmpp * Impp))
[1] 0.961

```

The function `prodGCPV` integrates the calculation procedure of irradiation, irradiance and simulation of the GCPV system. It constructs an object of class `ProdGCPV`.

The next code computes the productivity of the previous GCPV system working as fixed, NS horizontal axis tracking and two-axis tracking systems. The parameters of the generator, module, inverter and rest of the system are those by default in `prodGCPV`. The comparative of the performances is shown at the figure 11.

```

> lat = 37.2
> G0dm = c(2766, 3491, 4494, 5912, 6989, 7742, 7919, 7027, 5369,
+       3562, 2814, 2179)
> Ta = c(10, 14.1, 15.6, 17.2, 19.3, 21.2, 28.4, 29.9, 24.3, 18.2,
+       17.2, 15.2)
> prom = list(G0dm = G0dm, Ta = Ta)
> ProdFixed <- prodGCPV(lat = lat, prom = prom, keep.night = FALSE)
> Prod2x <- prodGCPV(lat = lat, prom = prom, modeTrk = "two", keep.night = FALSE)
> ProdHoriz <- prodGCPV(lat = lat, prom = prom, modeTrk = "horiz",
+       keep.night = FALSE)

```

4.1 Shadows

The shadows on PV generators alter the performance of the PV generators and reduce their productivity [5]. This package includes functions for the estimation of mutual shadows between generators from a same system. `fSombra2X`, `fSombraHoriz`, `fSombraEst`, calculate the shadows in two-axis, horizontal axis and fixed systems, respectively. The function `fSombra6` is indicated for groups of 6 two-axis trackers. Finally, `fSombra` is a wrapper to the previous functions.

For example, the shadows factor of a tracker surrounded by five trackers is calculated in the next code box. The dimensions of the tracker structure and the configuration (rows and columns) of the plant are defined by `struct`, while the distances between the trackers are defined by `distances`. The figure 12 shows the evolution of the shadows factor during the day (X axis) and year (Y axis).

Since the `data.frame` `distances` does only have one row, the function `fSombra6` builds a symmetric grid around the point (0,0,0), which is the affected tracker. This grid can also be constructed with:

```

> distances = data.frame(Lew = c(-40, 0, 40, -40, 40), Lns = c(30,
+       30, 30, 0, 0), H = 0)
> ShdFactor2 <- fSombra6(Angles, distances, struct, prom = FALSE)
> identical(coredata(ShdFactor), coredata(ShdFactor2))
[1] TRUE

```

Besides, `distances` can define a irregular grid around the affected tracker. Since this tracker is situated at (0,0,0), `distances` must have five rows. When `prom=TRUE`, `fSombra6` provides a weighted averaged of the shadows in the whole set of trackers, whose distribution in the PV plant is defined by `Nrow` y `Ncol`.

These functions are integrated in `calcShd`, `calcGef` and `prodGCPV`, as these examples show:

```

> ComparePac <- CBIND(two = as.zooI(Prod2x)$Pac, horiz = as.zooI(ProdHoriz)$Pac,
+   fixed = as.zooI(ProdFixed)$Pac)
> AngSol = as.zooI(as(ProdFixed, "Sol"))
> ComparePac = CBind(AngSol, ComparePac)
> mon = month(index(ComparePac))
> p = xyplot(two + horiz + fixed ~ AzS | mon, data = ComparePac,
+   type = "l", auto.key = list(space = "right", lines = TRUE,
+   points = FALSE), ylab = "Pac")
> print(p)

```

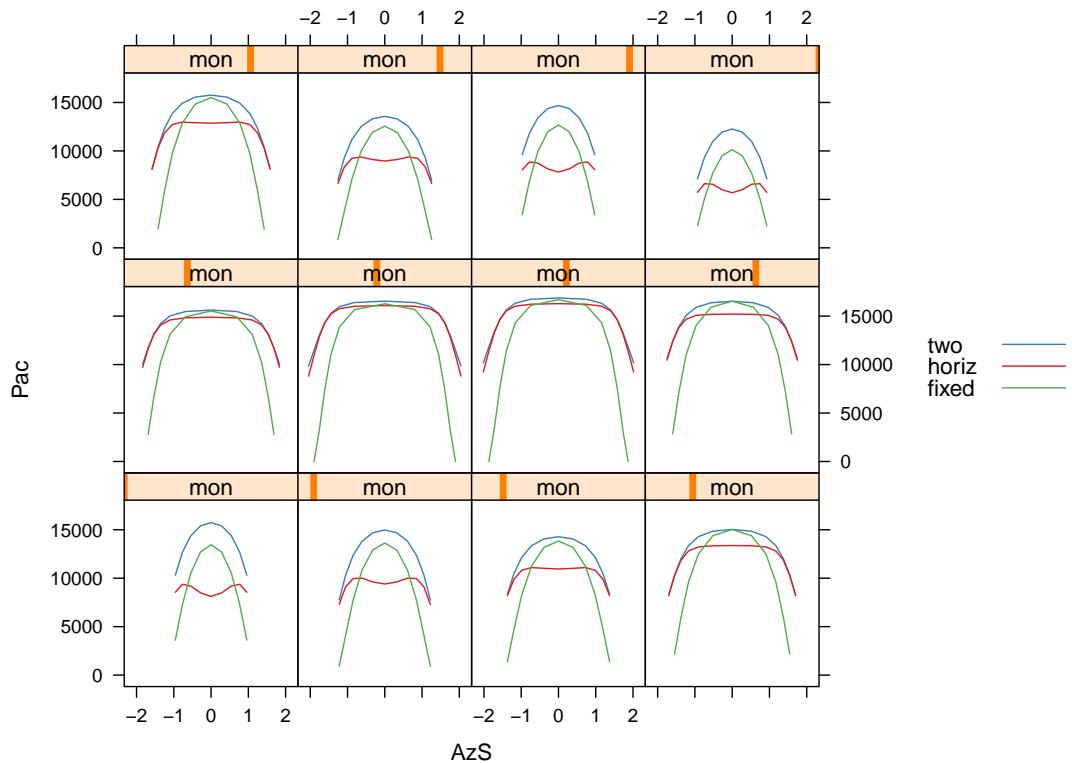

Figure 11: Comparative of performance between tracker strategies.

```
> p <- levelplot(FS ~ w * day, data = Angles, par.settings = custom.theme(region = brewer.pal("YlOrBr",
+ n = 9)))
> print(p)
```

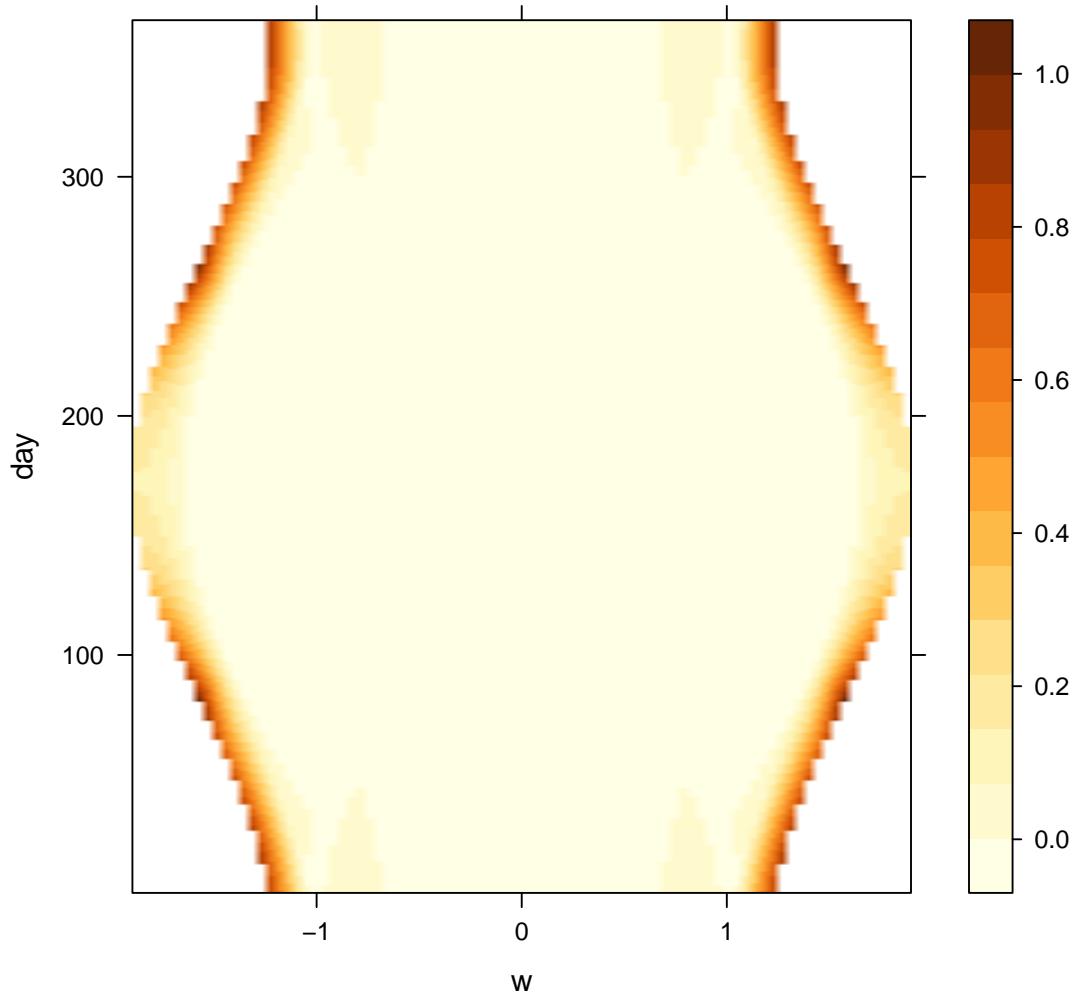

Figure 12: Shadows in a PV plant with two-axis trackers.

```
> struct2x = list(W = 23.11, L = 9.8, Nrow = 2, Ncol = 8)
> dist2x = data.frame(Lew = 40, Lns = 30, H = 0)
```

```
> prod2xShd <- prodGCPV(lat = lat, prom = prom, modeTrk = "two",
+   modeShd = "area", struct = struct2x, distances = dist2x)
> print(prod2xShd)
```

Finally, we can compare these systems with the method `compare` (fig. 13), and calculate and compare their losses with the methods `losses` and `compareLosses` (fig. 14), respectively.

4.2 Position of trackers in a PV plant

The optimum distance between trackers or static structures of a PV grid connected plant depends on two main factors: the ground cover ratio (defined as the ratio of the PV array area to the total ground area), and the productivity of the system including shadow losses. Therefore, the optimum separation may be the one which achieves the highest productivity with the highest ground cover ratio. However, this definition is not complete since the terrain characteristics and the costs of wiring or civil works could alter the decision.

The function `optimShd` is a help for choosing this distance: it computes the productivity for a set of combinations of distances between the elements of the plant [5]. The designer should adopt the decision from these results with the adequate economical translations.

Let's analyse the configuration of a PV plant with NS horizontal axis trackers, without *backtracking*, and a height of 4,83 m. We are interested in a range of separations of 2 and 5 times this dimension. Besides, the analysis will be carried out with a limitation in the angle of inclination:

```

```

The function `optimShd` constructs an object of class `Shade`. This class owns a S4 method of `plot` for displaying the results (figure 15).

Now, for a fixed system (figure 16):

```
> plot(Shd12Horiz)
```

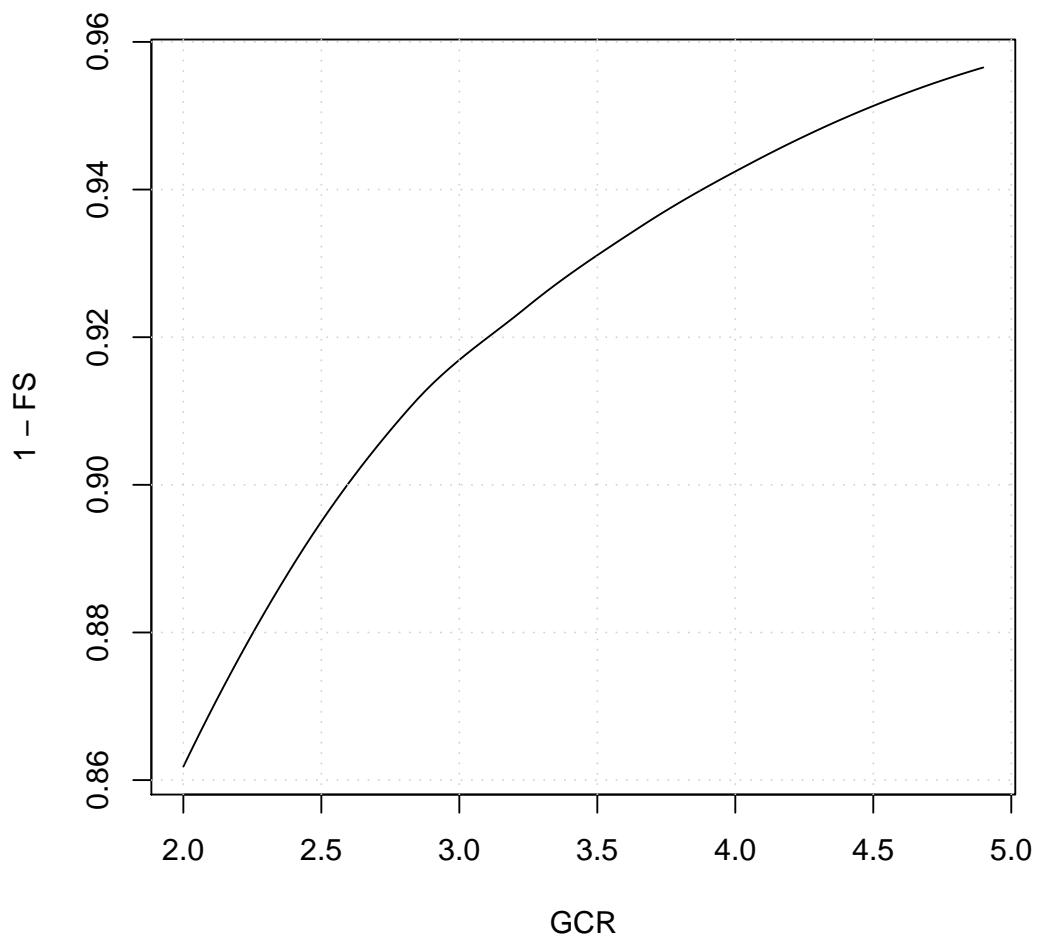

Figure 15: Mutual shadows in a NS horizontal axis tracking PV system.

```

> structFixed = list(L = 5)
> distFixed = list(D = structFixed$L * c(1, 3))
> Shd12Fixed <- optimShd(lat = lat, prom = prom, modeTrk = "fixed",
+   distances = distFixed, res = 1, struct = structFixed, modeShd = "area",
+   prog = FALSE)
> print(Shd12Fixed)

```

Last, we are interested in a two-axis tracker 23,11 m width and 9,8 m height. We will try to design a PV plant with a grid of 2 rows and 8 columns.

```
> struct2x = list(W = 23.11, L = 9.8, Nrow = 2, Ncol = 8)
```

We will try the separations between 30 m and 50 m for the E-O direction and between 20 m and 50 m for the N-S direction.

```
> dist2x = list(Lew = c(30, 50), Lns = c(20, 50))
```

The results are obtained with a resolution of 5 m (figure 17):

```
> plot(Shd12Fixed)
```

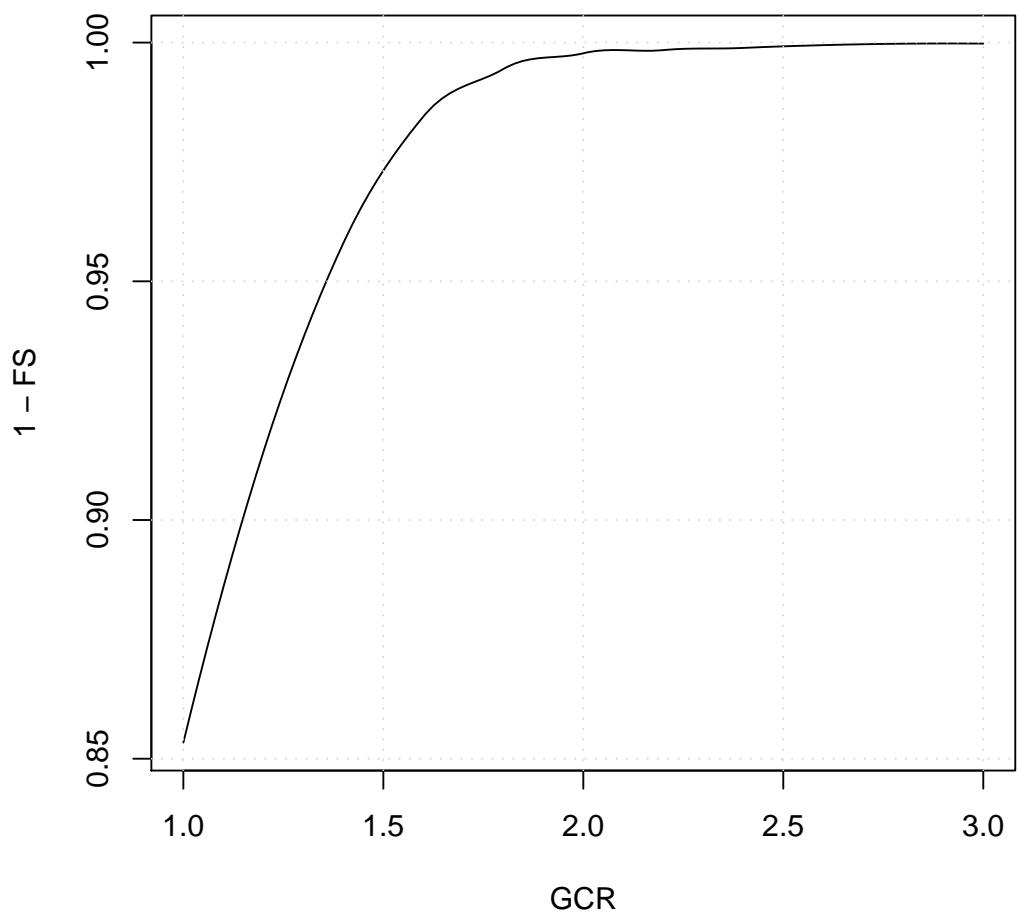

Figure 16: Mutual shadows in a PV plant with fixed structures.

5 PV pumping systems

5.1 Simulation of centrifugal pumps

The first step for the simulation of the performance of a PV pumping system (PVPS) is the characterization of the pump under the supposition of constant manometric height [1]. With the function fPump compute the performance of the different parts of a centrifugal pump fed by a frequency converter following the affinity laws.

```
> plot(ShdM2x)
```

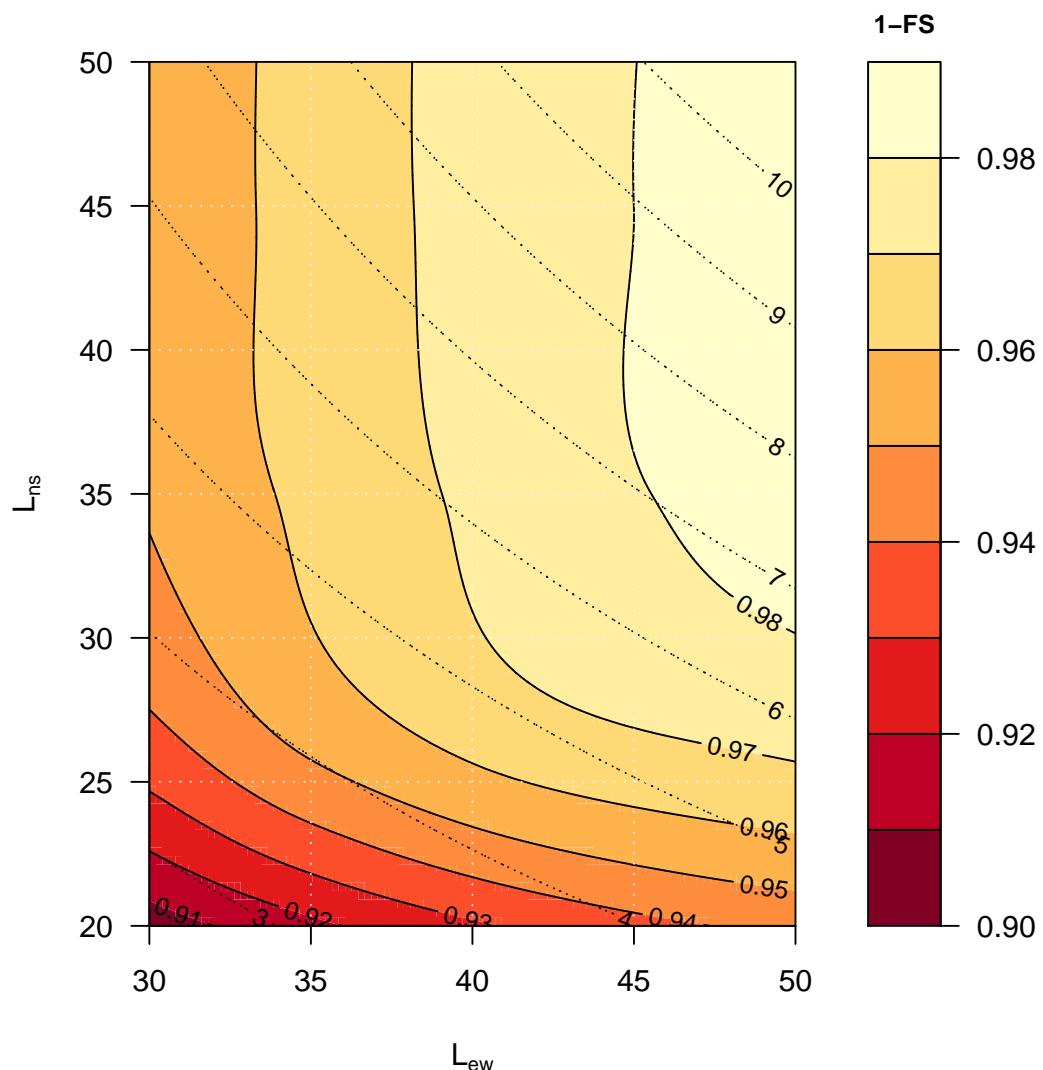

Figure 17: Mutual shadows in a two-axis tracking PV system for a combination of separations between trackers.

For example, with the function `fPump` we can characterize the performance of the SP8A44 pump (<http://net.grundfos.com/App1/WebCAPS/InitCtrl?mode=1>) working with $H = 40$ m. The information of this pump is stored in the dataset `pumpCoef`.

```
> data(pumpCoef)
> CoefSP8A44 <- subset(pumpCoef, Qn == 8 & stages == 44)
> fSP8A44 <- fPump(pump = CoefSP8A44, H = 40)
```

The result of `fPump` is a set of functions which relate the electrical power and the flow, hydraulical and mechanical power, and frequency. These functions allow the calculation of the performance for any electrical power inside the range of the pump (figures 18 and 19):

```
> SP8A44 = with(fSP8A44, {
+   Pac = seq(lim[1], lim[2], by = 100)
+   Pb = fPb(Pac)
+   etam = Pb/Pac
+   Ph = fPh(Pac)
+   etab = Ph/Pb
+   f = fFreq(Pac)
+   Q = fQ(Pac)
+   result = data.frame(Q, Pac, Pb, Ph, etam, etab, f)
+ })
> SP8A44$etamb = with(SP8A44, etab * etam)
```

5.2 Nomograms of PVPS

The international standard IEC 61725 is of common usage in public licitations of PVPS. This standard proposes a equation of the irradiance profile with several parameters such as the length of the day, the daily irradiation and the maximum value of the irradiance. With this profile, the performance of a PVPS can be calculated for several manometric heights and nominal PV power values. A nomogram can display the set of combinations. This graphical tool can help to choose the best combination of pump and PV generator for certain conditions of irradiation and height Abella.Lorenzo.ea2003.

This kind of graphics are provided by the function `NmgPVPS`. For example, the 20) is a nomogram for the SP8A44 pump working in a range of heights from 50 to 80 meters, with a different PV generators. The peculiar shape of the curve of 50 meters shows that this pump does not work correctly with this height.

5.3 Productivity of PVPS

A different approach is to simulate the performance of the PVPS following the same procedure as the one described for the GCPV systems. The function `prodPVPS` is the equivalent to the function `prodSFCR`. The inputs are very similar between them, although there are some changes due to the different composition of the system. This function does not allow the calculation of shadows.

Once again with the SP8A44 pump, we compute the flow to be provided by this pump with a PV generator of 5500 W_p and a manometric height of 50 meters. The relation between flow and effective irradiance is displayed in the figure 21.

```

> lab = c(expression(eta[motor]), expression(eta[pump]), expression(eta[mp]))
> p <- xyplot(etam + etab + etamb ~ Pac, data = SP8A44, type = "l",
+   ylab = "Eficiencia")
> print(p + glayer(panel.text(x[1], y[1], lab[group.number], pos = 3)))

```

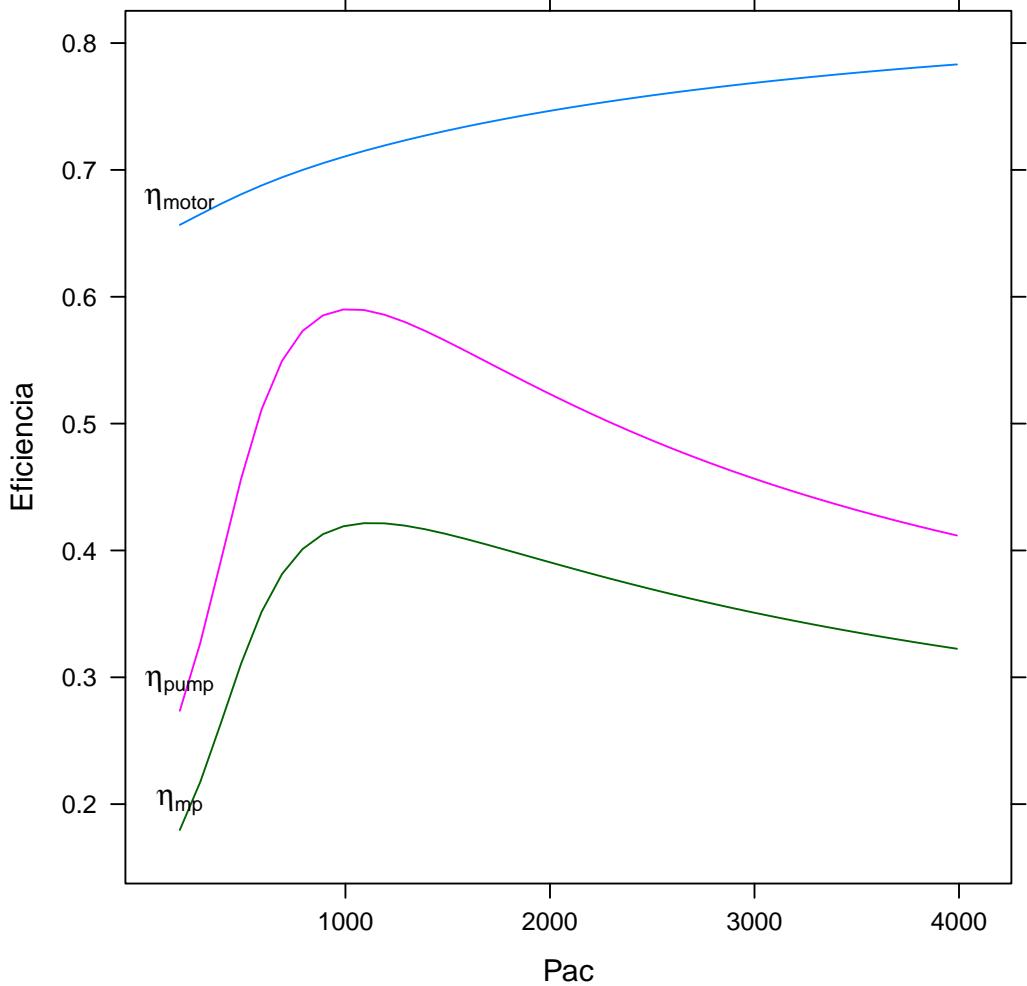

Figure 18: Efficiency of the motor and pump for several values of electrical power of a SP8A44 pump with $H = 40\text{ m}$

```

> lab = c(expression(P[pump]), expression(P[hyd]))
> p <- xyplot(Pb + Ph ~ Pac, data = SP8A44, type = "l", ylab = "Power (W)",
+   xlab = "AC power (W)")
> print(p + glayer(panel.text(x[length(x)], y[length(x)], lab[group.number],
+   pos = 3)))

```

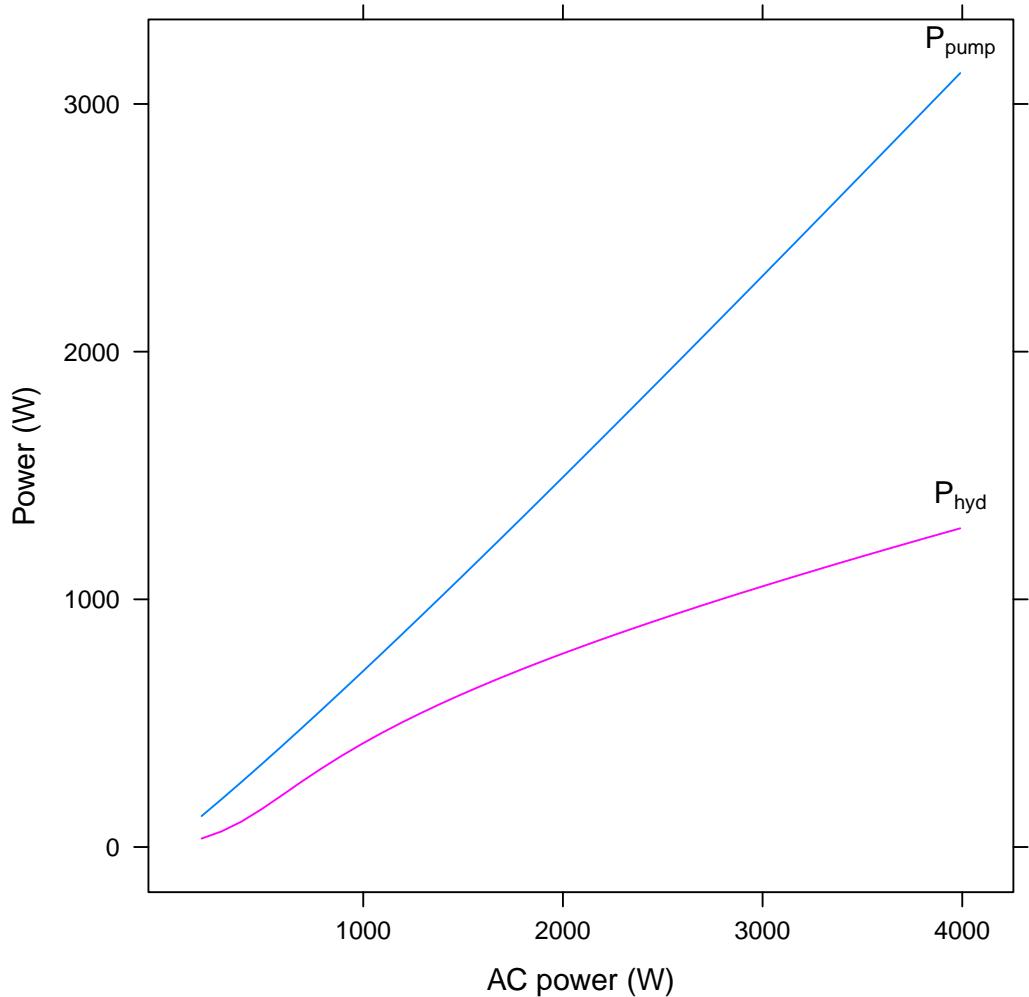

Figure 19: Mechanical and hydraulical power versus electrical power of a SP8A44 pump with $H = 40$ m.

```

> Pg = seq(3000, 5500, by = 500)
> H = seq(50, 80, by = 5)
> NmgSP8A44 <- NmgPVPS(pump = CoefSP8A44, Pg = Pg, H = H, Gd = 6000,
+ title = "Selection of Pumps", theme = custom.theme())
> print(NmgSP8A44$plot)

```

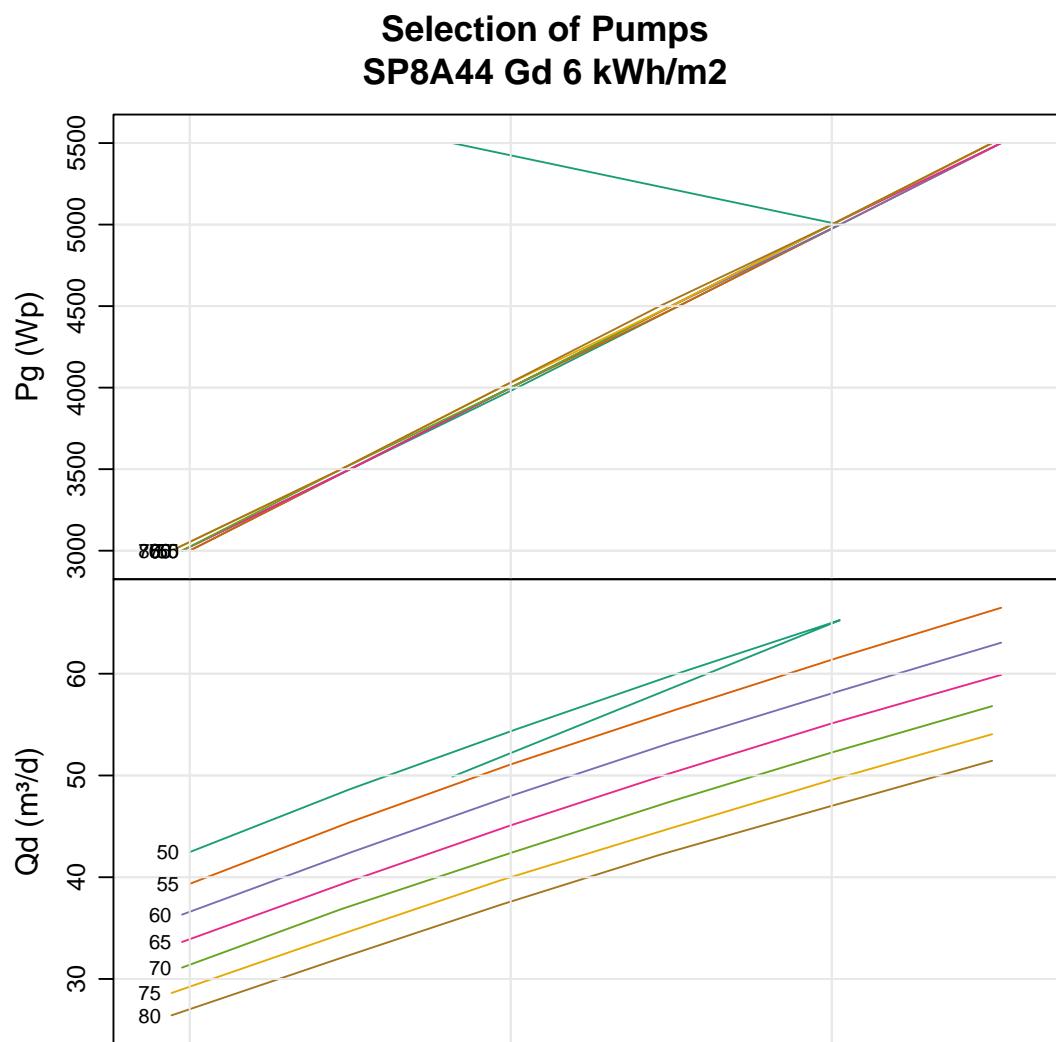

Figure 20: Nomogram for the SP8A44 pump working in a range of heights from 50 to 80 meters, with a different PV generators.

```

> prodSP8A44 <- prodPVPS(lat = 41, modeRad = "mapa", mapa = list(prov = 28,
+   est = 3, start = "01/01/2009", end = "31/12/2009"), pump = CoefSP8A44,
+   Pg = 5500, H = 50)

```

Let's try to obtain more water with this pump using a larger PV generator of 7000 Wp. However, we can check that this is not a correct decision. Both the productivity and the water flow have decreased. The figure 22 shows that during the central months of the year, during the maximum irradiance periods, the pump reaches its limits of flow and frequency, and so the frequency converter stops the system.

```

> prodSP8A44Lim <- prodPVPS(lat, modeRad = "prev", prev = prodSP8A44,
+   pump = CoefSP8A44, H = 50, Pg = 7000)

```

6 Statistical analysis of PV plants

In a PV plant, the individual systems are theoretically identical and their performance along the time should be the same. Due to their practical differences –power tolerance, dispersion losses, dust–, the individual performance of each system will deviate from the average behaviour. However, when a system is performing correctly, these deviations are constrained inside a range and should not be regarded as sign of malfunctioning.

If these common deviations are assumed as a random process, a statistical analysis of the performance of the whole set of systems can identify a faulty system as the one that departs significantly from the mean behaviour.

The functions `analyzeData` and `TargetDiagram` compare the daily performance of each system with a reference (for example, the median of the whole set) during a time period of N days preceding the current day. They calculate a set of statistics of the performance of the PV plant as a whole, and another set of the comparison with the reference. This statistical analysis can be summarised with a graphical tool named "Target Diagram", which plots together the root mean square difference, the average difference and the standard deviation of the difference. Besides, this diagram includes the sign of the difference of the standard deviations of the system and the reference [6].

The next example uses a dataset of productivity from a PV plant composed of 22 systems (`data(prodEx)`). It is clear that the system no.22 is not working correctly during these periods (figure 24).

```

> data(prodEx)
> prodStat <- analyzeData(prodEx)

```

```

> p = xyplot(Q ~ Gef / month, data = prodSP8A44, cex = 0.5, type = c("p",
+   "smooth"), col.symbol = "gray", col.line = "black")
> print(p)

```

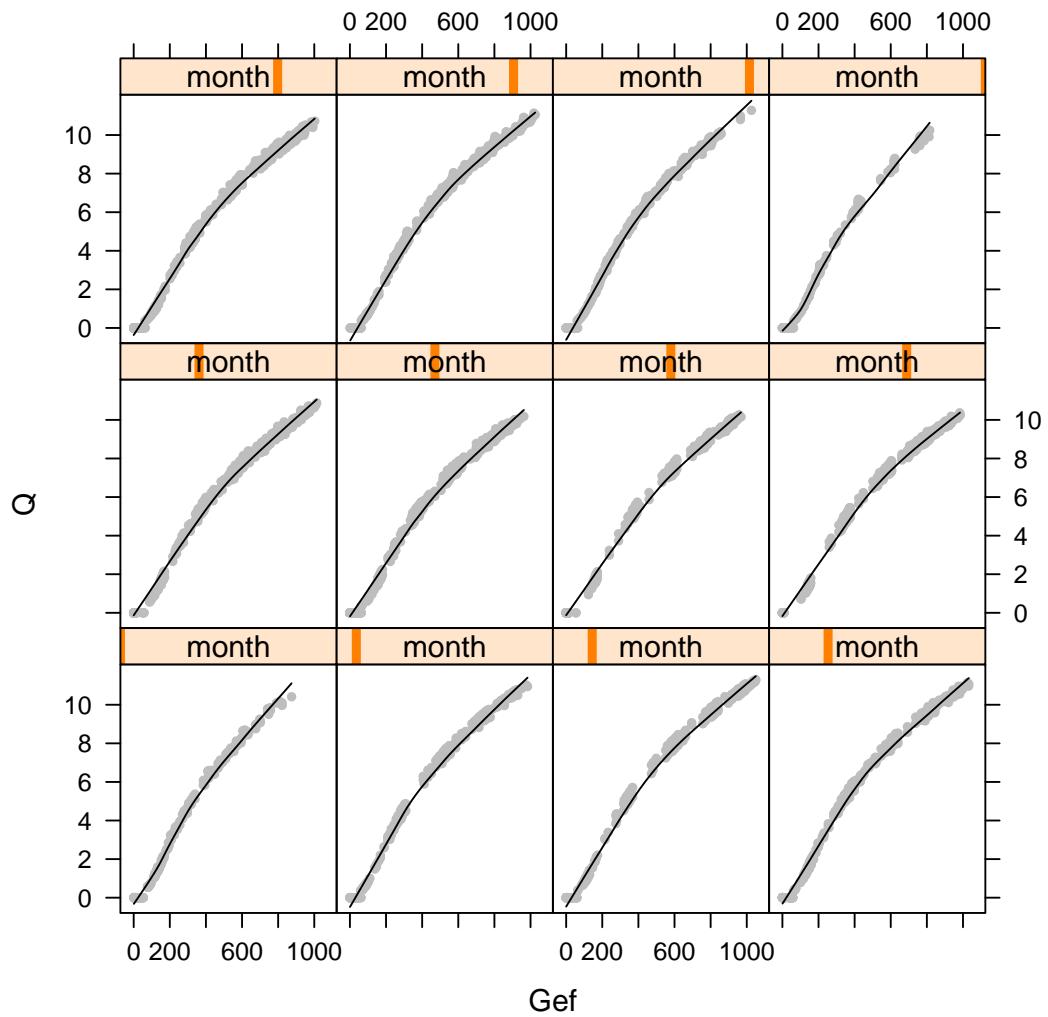

Figure 21: Flow versus irradiance of a PVPS with a SP8A44 pump and a PV generator with a nominal power of 5500 Wp and a manometric height of 50 meters.

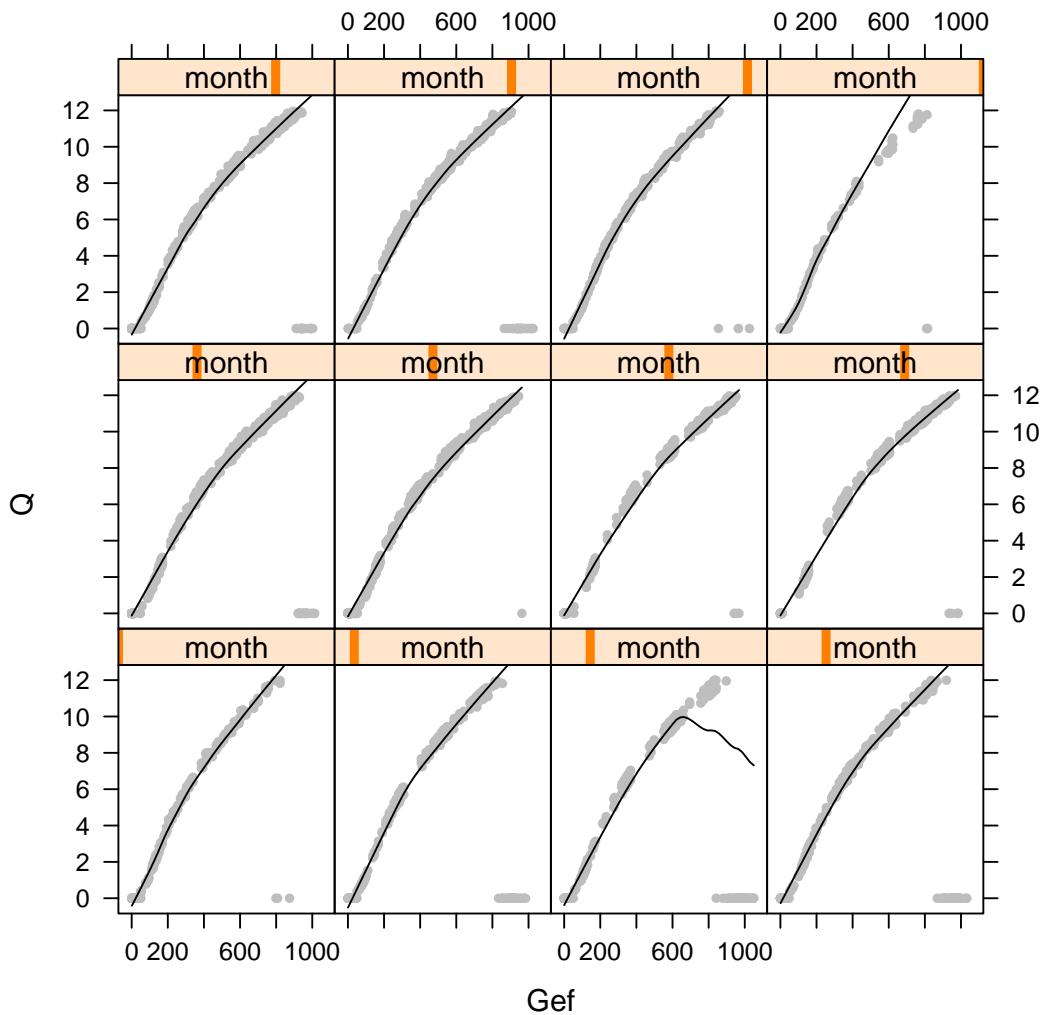

Figure 22: Water flow versus irradiance of a PVPS system with a SP8A44 pump and a generator of 7000 Wp with a manometric height of 50 meters.

```
> p = xyplot(prodStat$stat)
> print(p)
```

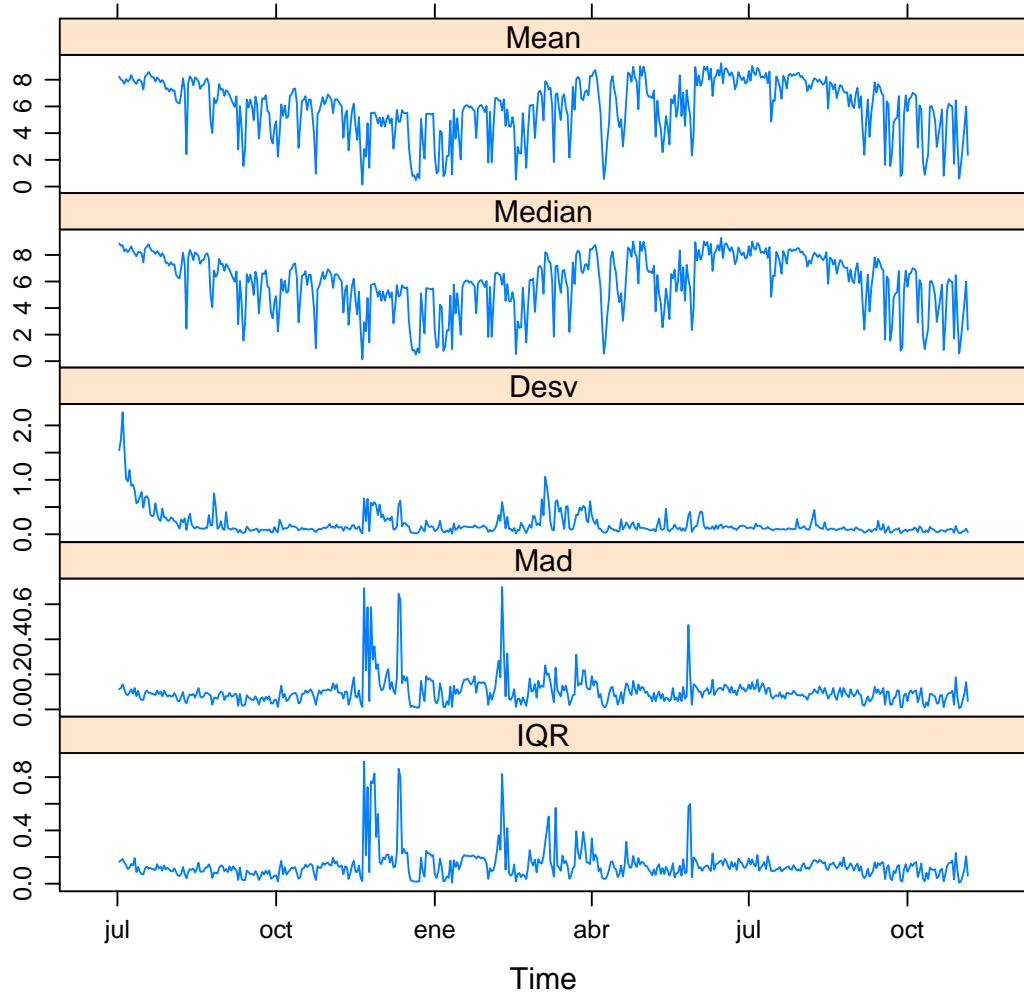

Figure 23: Statistical analysis of a set of 22 PV systems.

```

> day = as.Date("2008-8-29")
> ndays = c(5, 10, 15, 20)
> palette = brewer.pal(n = length(ndays), name = "Set1")
> TDColor <- TargetDiagram(prodEx, end = day, ndays = ndays, color = palette)
> print(TDColor$plot)

```

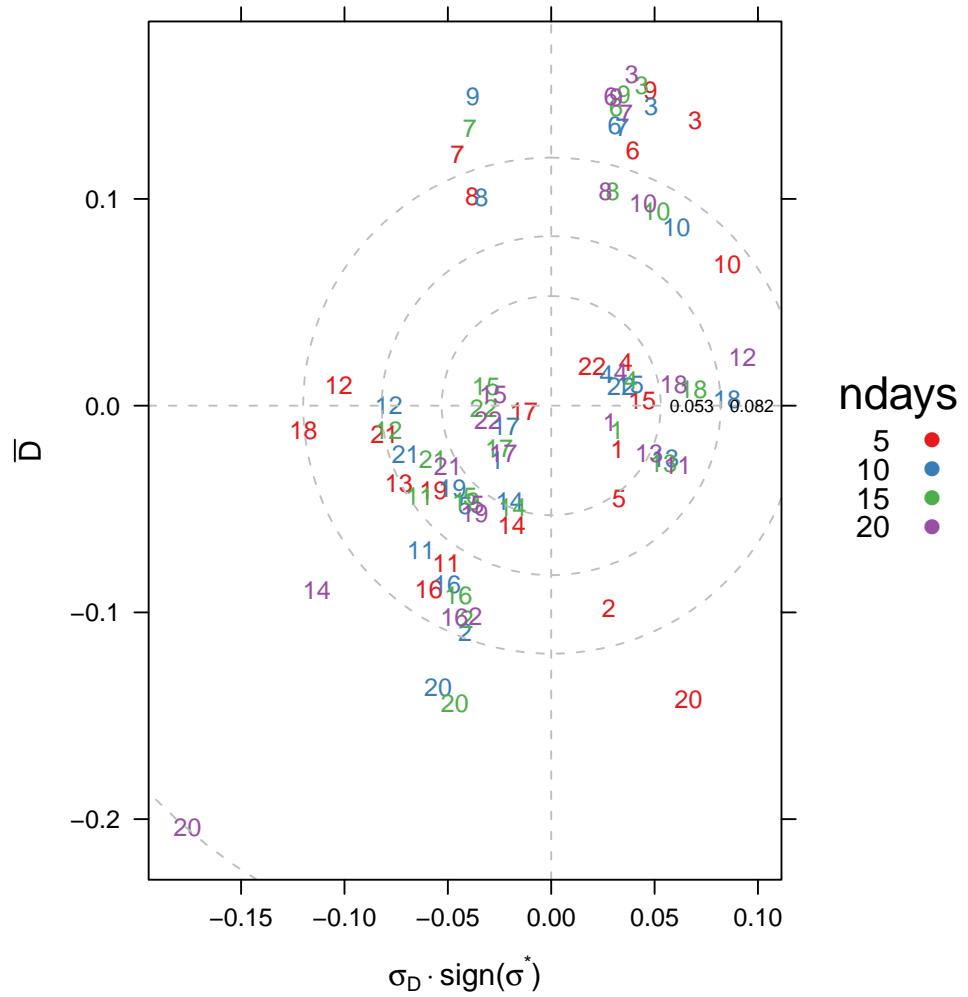

Figure 24: “Target Diagram” of the statistical analysis of a set of 22 systems during various time periods.

7 Changes

solaR 0.21

solaR is now able to calculate from both daily and sub-daily irradiation values. Besides,

- calcSol and fSolI gain a "BTi" argument for intradaily time bases.
- fCompI gains a "GOI" argument for intradaily irradiation series.
- fCompI gains both "corr" and "f".
- calcG0, calcGef, prodGCPV and prodPVPS gain a new "bdI" argument for intradaily irradiation, and the "corr", "f" arguments.
- The "bd" (and the new "bdI") argument of "calcG0" can be now a "Meteo" object. The "file" component of this argument can be now a "zoo" object.
- New methods ("losses", "compareLosses" and "compare") are available for "Gef" and "ProdGCPV" classes.
- The "corr" argument of "fCompD" (and "fCompI") can be now "corr=none".
- The correlations between the diffuse fraction and the clearness index are now coded outside "fCompD" as separate functions. Several new correlations have been included, both for monthly/daily values and for intradaily values.
- New small functions for difftime objects have been included.

solaR 0.20

- The package is now almost entirely designed with S4 classes and methods.
- The time series object are constructed with the 'zoo' package.
- Most of the functions and arguments have been renamed in order to ease the understanding by international users.
- Two new functions have been included for the statistical analysis of a PV plant composed of several systems.
- The package dependencies have been optimized.
- Several new small functions for date-time calculations are now available.
